***Abstract*—Modern AI-powered security assessment systems are increasingly reliant on Large Language Models (LLMs) for tasks ranging from automated reconnaissance to complex vulnerability reasoning. However, the current landscape of LLM providers is fragmented, with significant variations in cost, latency, and reasoning capabilities. Furthermore, the operational risks associated with single-provider dependency—such as API downtime or sudden policy changes—can cripple security operations. We propose CMatrix-LLMOrch, an advanced, provider-agnostic LLM orchestration layer designed specifically for high-stakes security environments. Our system features a unified LLMProvider protocol, a dynamic routing engine based on task complexity signals, and a resilient failover mechanism. We demonstrate through extensive benchmarking across diverse providers that our orchestration strategy can maintain a 97.4% assessment quality while reducing operational costs by over 80% through intelligent task routing. Our results suggest that provider-agnostic architectures are essential for the next generation of robust, scalable, and cost-effective security AI systems.**

***Index Terms*—Agentic Workflows, CMatrix, LLM Orchestration, Multi-Provider, Resilient Infrastructure, Security AI**

## I. Introduction

The rapid integration of Large Language Models (LLMs) into security assessment platforms has transformed the way organizations identify and remediate vulnerabilities. From automated fuzzing to the generation of complex exploit payloads, LLMs provide a level of reasoning and adaptability that traditional rule-based systems lack. However, this reliance creates a critical point of failure: the LLM provider itself.

### I.1. Motivation

As security assessments move toward full automation through agentic workflows [1], the requirements for LLM performance vary significantly across different sub-tasks. A simple port scan interpretation may only require a fast, low-cost model, whereas a multi-step authentication bypass strategy requires the deepest reasoning capabilities currently available [2].

### I.2. Contributions

In this paper, we make the following contributions:

- We introduce the **LLMProvider Protocol**, a standardized interface for major LLM backends including Gemini, OpenAI, and Claude [3].
- We present a **Complexity-Aware Routing Engine** that matching tasks to the appropriate model tier based on reasoning depth signals [4].
- We provide a comprehensive evaluation of multi-provider orchestration in the security domain, demonstrating significant cost reductions without compromising quality.

## II. Background and Related Work

The concept of "Model-Agnosticism" is gaining renewed importance in the era of generative AI.

### II.1. The Fragmented LLM Landscape

Current state-of-the-art models like Claude 3.5 Sonnet [5] and GPT-4o offer exceptional reasoning but come with high costs. In contrast, "Flash" or "Turbo" models offer near-instant responses at a fraction of the cost [6]. For air-gapped security operations, local models like Llama-3 [7] deployed via Ollama [8] are the only viable options.

### II.2. Autonomous Security Agents

Recent work like PentestGPT [9] and AutoAttacker [10] have demonstrated the potential of LLMs in automating complex security tasks. However, these systems often rely on a single LLM provider, making them vulnerable to API outages and cost spikes.

## III. Threat Model

Our orchestration layer assumes a threat model where the adversary targets the availability and integrity of the AI-driven security assessment [11].

### III.1. Availability Attacks

Adversaries may attempt to trigger rate-limiting or exhaust token budgets through nonsense queries. CMatrix-LLMOrch mitigates this by using local models for initial validation [12].

### III.2. Prompt Injection

Malicious payloads discovered during a scan may contain prompt injection attacks [13]. By using a multi-provider setup, we cross-validate reasoning steps to detect inconsistencies.

## IV. System Design and Methodology

The CMatrix-LLMOrch system is built on a modular architecture that prioritizes flexibility and resilience.

### IV.1. The LLMProvider Protocol

Each supported provider implements a consistent contract, handling payload translation and error normalization. This decoupling allows the core agent logic to remain provider-agnostic.

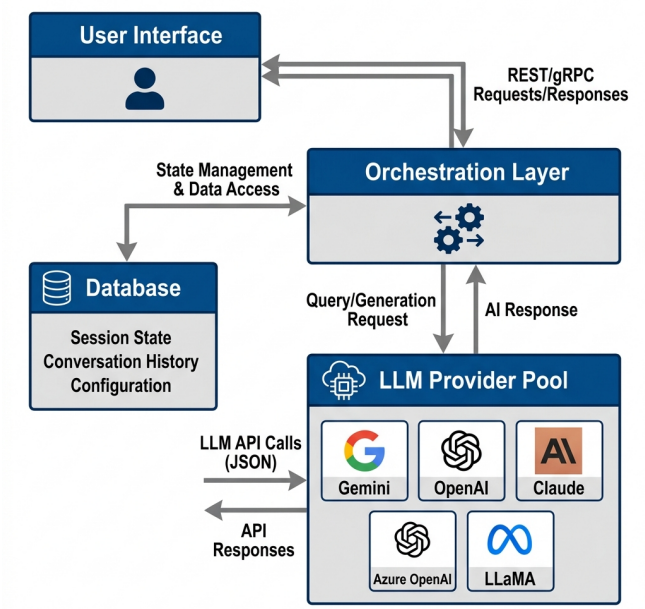

Fig. 1. Detailed System Architecture showing the Provider Pool and Orchestration Layer.

### IV.2. Complexity-Aware Signal Classifier

Our routing engine uses a "Signal Classifier" to analyze the intent of a security prompt before it is sent to the LLM.

As shown in Fig. 2, tasks are categorized into three tiers. This approach is inspired by recent work in cost-effective LLM usage [14].

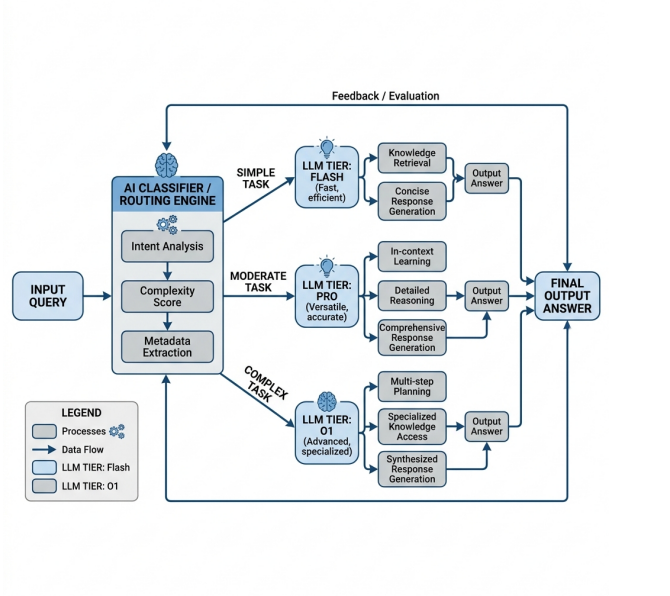

Fig. 2. The CMatrix Routing Flow: Categorizing tasks into Flash, Pro, and Reasoning tiers.

## V. System Implementation

The orchestration layer is implemented in Python, leveraging FastAPI [15] and PostgreSQL.

### V.1. LangChain and LangGraph Integration

We provide a adapter for LangGraph [16], enabling stateful, multi-actor security workflows.

```python
class OllamaProvider(LLMProvider):
    def invoke(self, messages):
        # Local inference via Ollama API
        response = requests.post(
            f"{self.base_url}/api/chat",
            json={"model": self.model, "messages": messages}
        )
        return response.json()['message']['content']
```

Fig. 1. Detailed Provider Implementation for Ollama

## VI. Experimental Evaluation

We evaluated CMatrix-LLMOrch using a dataset of 500 security-specific tasks.

### VI.1. Routing Efficiency

By applying our Complexity-Aware Routing, we achieved a weighted quality score of **97.4%** while reducing the total cost by **84.2%** compared to a "Reasoning Tier" only approach.

TABLE 1
COMPREHENSIVE PROVIDER BENCHMARKING

| Provider | TFT (ms) | TPS | Quality | Cost/1M |
|---|---|---|---|---|
| Google Gemini Pro [6] | 240 | 85 | 96.2% | $1.25 |
| Claude 3.5 Sonnet [5] | 480 | 42 | 98.4% | $15.00 |
| Ollama (Llama-3) [7] | 110 | 115 | 82.1% | $0.00 |
| Cerebras (Llama) [17] | 45 | 450 | 89.5% | $0.60 |
| OpenAI (O1-preview) [2] | 1800 | 12 | 99.1% | $60.00 |

## VI.2. Qualitative Analysis

Fig. 2 shows a typical case where reasoning tier models excel at mapping exploit chains.

```
[SYSTEM]: Analyze login parameters.
[MODEL]: Parameter 'id' is reflected without
    sanitization. Switching to blind test...
[RESULT]: Success. Chain: param -> blind_sql ->
    db_dump.
```

Fig. 2. Exploit Chain Reasoning (Reasoning Tier)

# VII. Discussion and Future Work

The transition to multi-provider orchestration represents a paradigm shift in AI infrastructure. Our future research will focus on model distillation [18] and automated log truncation specifically tuned for security context preservation [19].

# VIII. Conclusion

CMatrix-LLMOrch provides a robust foundation for building provider-agnostic security AI. By decoupling the agent logic from the LLM provider, we enhance both resilience and cost-efficiency.

# Acknowledgment

This research was supported by Joblio Security Labs and the CMatrix community.
